Previous (Binomial nomenclature). Next (Biodiversity). Biochemistry (once known as physiological chemistry or biological chemistry) is the study of chemicals and chemical processes that occur in living organisms. It involves investigation of the structures, functions, and syntheses of biological substances, including proteins, DNA (deoxyribonucleic acid), RNA (ribonucleic acid), carbohydrates, lipids, nucleotides, and amino acids. Research in biochemistry has revealed the functions of groups of The following outline is provided as an overview of and topical guide to biochemistry: Biochemistry – study of chemical processes in living organisms, including living matter. Biochemistry governs all living organisms and living processes. Testing. Ames test – salmonella bacteria is exposed to a chemical under question (a food additive, for example), and changes in the way the bacteria grows are measured. This test is useful for screening chemicals to see if they mutate the structure of DNA and by Biochemistry applies chemistry concepts to the study of living organisms and the atoms and molecules that comprise them. Biochemistry is the branch of science concerned with the chemistry of biological processes. It attempts to utilize the tools and concepts of chemistry, particularly organic and physical chemistry, for elucidation of living systems. The science has been variously referred to as physiological chemistry and as biological chemistry. Biochemists study such things as the structures and physical properties of biological molecules, including the proteins, the carbohydrates, the lipids, and the nucleic acids Previous (Binomial nomenclature).
