Large companies have significantly improved the security of the network perimeter, but despite their investments in that area, most large networks remain vulnerable at their core. Techniques that have proved successful at defending the perimeter have not been effective internally, as a result of both scalability and perspective issues. However, security practitioners can make major strides in fortifying their internal networks by aligning their tactics with the realities of internal network security. The following 10 tips illustrate ways to address the security challenges of large, active inte

Expert Johna Johnson explores how network perimeter security, facing porous borders, BYOD and blurring of boundaries is evolving into perimeterless security.Â The concept of "inside" and "outside" an enterprise network perimeter is dated. Expert Johna Johnson explores how network perimeter security must change to deal with increasingly porous borders, cloud, BYOD and other network developments. Video. Physical security perimeters should be implemented to safeguard sensitive data and information systems. These can include fences, walls, barriers, guards, gates, electronic surveillance, physical authentication mechanisms, badges, fingerprint scanners, reception desks, and security patrols (CSA, 2015).Â Firewalls are a perimeter security device that limits the ingress and egress of data and connections, primarily based on the network services. That is an oversimplification of the functionality, however for the purposes of this chapter, it is sufficient. Firewalls can be very useful in easing the security burden on individual systems. The network perimeter is less tangible in an actual network environment (thus the previous use of superfluous metaphor). Networking devices are commonly located in a single server room or data center, or perhaps are located in a hybrid of in-house and cloud-based locations.Â Network-based firewalls are primarily used to section off and protect one network from another. They are a primary line of defense and are extremely important in network security.Â You would be in front of the drawbridge, and the people inside the castle would be behind the drawbridge. This is a basic analogy but should help you to understand the whole "in front of" and "behind" business as it relates to data attempting to enter the network and devices that reside on your network. For decades, network security philosophy focused on securing the inside from threat actors on the outside, which was the same philosophy the Romans relied on to protect their frontier. Defining perimeters made sense in the early days of network security and aligned with the basic principle of defense-in-depth – protect internal resources from external forces. It worked because employees were office-bound, and the office walls defined the perimeter that protected the resources they were trusted to access. Step outside, and employees became intruders if they tried to access those very same resources.

Originally, security architectures were predicated on the notion that network perimeter security could be established on the "inside" (private circuits, servers, routers and devices residing on a user's premise that security professionals control) and protected against threats from the "outside" (public networks and off-premises devices). The demarcation between inside and outside is, of course, the enterprise perimeter. Specifically, network perimeter security was enforced by the line of firewalls and other protective devices that physically insulated a company's
